## DETAILED DESCRIPTION OF THE INVENTION

The present invention generally pertains to a monolithic semiconductor device having a VCSEL integrated with a photodetector on the same substrate, wherein the VCSEL and photodetector are to be operated independently as transmit and receive devices respectively. The VCSEL and photodetector are physically situated in close enough proximity to permit packaging of one or more pairs of the VCSEL and photodetector such that they may be coupled to multifiber ferrules having fiber spacing on the order of 250 microns or less. The present invention also includes a method of manufacturing the independently operated VCSEL and photodetector, as well as the packaging and coupling of one or more pairs of the integrated VCSEL and photodetector to multifiber ferrules.

A first preferred embodiment of the invention is now discussed in detail in conjunction with Figures 3 and 4. As shown in Figure 3, a VCSEL and a metal -semiconductor-metal (MSM) photodetector are integrated on the same semi-insulating GaAs substrate 60. The conductance of the semi-insulating substrate 60 is typically between about $10^{-12}$ and $10^{-5}$ ohm-cm. The VCSEL is built on top of the substrate 60 beginning with an n- layer 68, upon which an n+ layer 70 is grown to form the cathode of the VCSEL.

A first mirror 78 is formed on n+ layer 70, which is preferably an epitaxially formed distributed Bragg reflector (DBR) which comprises a plurality of alternating semiconductor layers having high and low indices of refraction, with each layer having a thickness of $\lambda/4n$, where $\lambda$ is the wavelength of the optical radiation emitted from the

laser and n is the index of refraction of the layer. The semiconductor layers are doped to achieve n-type conductivity. A quantum well (QW) active region 74 is formed between a first spacer 73 and a second spacer 75, with first spacer 73 formed on the top layer of the first mirror 78. Active region 74 has at least one QW layer.

A second mirror 76 is formed on second spacer 75 and is preferably an epitaxially grown DBR which is comprised of a plurality of alternating semiconductor layers having high and low indices of refraction, with each layer having a thickness of $\lambda/4n$, where $\lambda$ is the wavelength of the optical radiation emitted from the laser and n is the index of refraction of the layer. The second mirror 76 is doped to achieve p-type conductivity. An isolation implant 81 is formed around the second mirror 76, and preferably extends to a depth just inside spacer 75. A mesa region is then etched around the outside of the VCSEL 89 to a depth that exposes the cathode layer 70. A cathode contact 72 is then formed on the exposed surface of n+ layer 70, and an anode contact 82 is formed which overlaps the surface of isolation implant region 81 and the topmost layer of second mirror 76, and which further defines an aperture 88 which comprises a portion of the surface of the top-most layer of second mirror 76. Radiation 84 is emitted through aperture 88.

The MSM photodetector 62 is formed on the surface of the semi-insulating substrate 60 as two non-electrically coupled metal patterns 66 and 64, each having fingers that are interdigitated with one another. When one or both of the patterns is biased to some voltage, carriers generated by received light are swept to the anodes of the two diodes by the applied electric field. Because the MSM 62 operates without conducting any current through the substrate 60, there is virtually no electrical crosstalk

or leakage between the VCSEL 89 and the MSM photodetector 62. Thus, the VCSEL 89 can emit radiation 84 from aperture 88 based on digital data to be transmitted while MSM photodetector 62 can receive radiation 86 in which is encoded digital data received from a remote data source. To achieve even better isolation, an isolation region 80 can be formed preferably by proton implant between VCSEL 89 and MSM photodetector 62.

Figure 4 illustrates a plan view of the device that is shown as a cross-section in Figure 3. For clarity, corresponding structures will be indicated by identical index numbers. The n+ layer 70 and its metal cathode contact 72 of the VCSEL are extended to the boundary of substrate 60, which is furthest away from MSM photodetector 62. Bond wire 71 can then be used to connect cathode contact 72 to a bond pad of, for example, a lead frame. The VCSEL anode contact 82 is brought to the same substrate boundary by bond wire 77, metal extender 79 and bond wire 69. Metal patterns 66 and 64, which form the anode and anode terminals of MSM photodetector 62, are also bonded to the leads of whatever form of packaging is used. One of the metal patterns is typically coupled to a bias voltage while the other is coupled to ground or a different bias voltage. An anti reflection coating can be employed on the MSM 62 to increase optical efficiency.

A second preferred embodiment is disclosed in Figure 5a. For convenience and clarity, like structures will be denoted by the same index numbers as in previous figures. This particular embodiment is preferred because it can be implemented using more standard VCSEL manufacturing processes. A first mirror 78 is formed on a standard semiconductor GaAs substrate 60. The first mirror is preferably a semiconductor DBR

comprising twenty to thirty periods of AlAs/AlGaAs layers. Each of the layers has a thickness of $\lambda/(4n)$ and is doped to have n-type conductivity. A first spacer or cladding layer 73 is then formed on first mirror 78, which is either undoped or very lightly doped. An active region 74 is then formed on the first spacer 73, which comprises at least one

5    GaAs QW layer. A second mirror 76 is then formed on top of a second undoped or very lightly doped spacer or cladding layer 75. The second mirror 76 again preferably consists of alternating layers of AlAs/AlGaAs layers, each being $\lambda/(4n)$ thick. Second mirror 76 is doped to have p-type conductivity. On top of second mirror 76 is formed a thin etch-stop layer 93, which has a significantly higher ratio of Al to Ga, about 9 to 1 or

10   greater. On top of the etch-stop layer 93, an extended p-type layer 100 of AlGaAs is formed. On top of p-type layer 100 is formed an intrinsic layer (i) 102 of undoped GaAs. Finally, an n-type layer 104 is formed on top of intrinsic layer 102.

The structure is then etched in those areas where a VCSEL is to be formed, and not etched where a p-i-n photodiode is to be formed. The etch strips away the n-type

15   layer 104 and intrinsic layer 102 and continues into p-type layer 100 until the etch-stop layer 93 is detected. The etching process is terminated so that the etch-stop layer 93 is etched away and an appropriately thick top layer of second mirror 76 is exposed. Those of skill in the art will recognize that there are other well-known techniques by which the endpoint of an etching process may be detected to end the etching process

20   at the appropriate time and which are intended to be within the scope of the present invention.

A proton isolation implant is performed to create isolation region 80 between VCSEL 92 and p-i-n photodiode 90. The implant region 80 typically achieves a depth,

which extends just inside spacer layer 75 and has a width preferably between about 50 and 100 microns. A circular metal contact 82 is then formed on the top of mirror 76 and which overlaps slightly implant region 80. Contact 82 provides access to the anode of VCSEL 92. A contact 81 is then formed on the backside of substrate 79 and serves as

5    the cathode terminal of VCSEL 92. Contacts 94 are preferably formed on both sides of p-i-n photodiode 90 which provide electrical access to the anode of p-i-n photodiode 90 as well as to the anode 98 of the VCSEL 91, which underlies p-i-n photodiode 90. Finally, contact 96 is formed on n-type layer 104 to form the cathode of p-i-n in photodiode 90. An anti-reflection coating preferably having a thickness of about one

10   quarter wavelength is applied to photo-receiving surface 101.

A simplified schematic of the structure of Figure 5a is shown in Figure 5b. VCSEL 92 is operated with forward bias between contact 82 and cathode terminal 98 to produce radiation 84 having a wavelength of $\lambda$. The p-i-n photodiode 90 is operated with reverse bias between cathode contact 96 and anode contacts 94. Moreover,

15   anode contacts 94 are shorted to substrate contact 98 to ensure that VCSEL 91 will not become forward biased and emit light. Thus, VCSEL 92 can be operated to emit light encoded with data to be transmitted to a remote receiver employing a similar structure, and p-i-n photodiode 90 can operate to receive radiation 86, which is encoded with data received from the same remote terminal.

20   Those of skill in the art will recognize that the exact order in which the process steps take place, as well as the particular material system used, are irrelevant to the patentability of the present invention. For example, one material system might include a GaAs substrate, GaAs quantum wells, DBR layers of AlAs and AlGaAs. Other known

material systems may be used to produce different wavelengths of emitted radiation and the particular dimensions of the integrated devices may be changed to suit the particular transmission modes or the packaging requirements. Moreover, although it is desirable that the photolothographically defined spacings between the transmit and

5   receive pairs are preferably small, of course larger spacings can be easily accommodated by the present invention.

Those of skill in the art will recognize many advantages of the second preferred embodiment of Figure 5a is that a typical process used to create arrays of VCSELs, including the isolation implant commonly used to separate the individual VCSELs of the

10  array, can be used to create arrays of VCSEL/p-i-n photodiode pairs. The additional steps required to build the p-i-n photodiode on top of the VCSEL process are negligible in cost. Moreover, the difference in the thickness of the two devices is also negligible for purposes of facilitating near-field coupling of the devices to fibers to eliminate the need for optics. Additionally, due to the underlying second mirror of inoperable VCSEL

15  91, any light not absorbed by the intrinsic layer 102 of p-i-n photodiode 90 will be reflected back into intrinsic layer 102, thus having a second chance to be absorbed. Finally, the thicker the intrinsic layer 102, the lower the capacitance of the p-i-n diode 90 (the faster its operation) and the better its optical efficiency.

Figure 6(a) illustrates how the commonly used single fiber round ferrule can be

20  implemented using two or more fibers. Such fibers are now currently available from Siecor as prototypes. The cylindrical ferrule 110 has the same dimensions (i.e., 2.5 mm) as those ferrules commonly used with only one fiber. Thus, one fiber 112 can be

used for transmitting data as coupled to a VCSEL while fiber 114 can be used to receive data from a remote transmitter as coupled to a photodetector.

Figure 6(b) illustrates a commonly available rectangular ferrule which can have eight or more fibers 122, and which has guides 120 for receiving alignment pins. Rectangular ferrule 116 typically has a polished face 118 for coupling to an array of transmitting VCSELs. This rectangular ferrule 116 can be easily adapted to devices made in accordance with the present invention, such that each pair of fibers 122 can be aligned with a pair of integrated VCSEL/photodetectors.

Figure 7(a) illustrates how a single VCSEL /photodetector pair could be packaged using standard lead-frame technology to be interfaced to a rectangular multifiber ferrule such as the one illustrated in Fig. 6(b). Integrated transmit/receive chip 130 can be epoxied to lead frame 128 and then bonded to bond pads 141 via bond wires 143. If optics are required, lenses 138 and 136 can be formed over VCSEL 89, 92 and photodetector 62,90 respectively, either using materials which are formed over chip 130 during the manufacturing of chip 130 or such optics can be integrated within the surface of the plastic encapsulation formed by the package. Lead frame 128 can also have guide pins 140 to be used in conjunction with a rectangular ferrule such as the one shown in Figure 6(b). Figure 7(b) shows a side view of Figure 7a to illustrate the use of optics over photodetector 62, 90 and VCSEL 89, 92.

Figure 7(c) illustrates how lead frame 128 can be butt coupled to a rectangular ferrule 150 containing two fibers 124 and 126. If distance 160 is fairly precisely known, and distance 147 between fibers 124 and 126 is fairly precise, a fairly accurate

alignment can be achieved between fibers 124 and 126 and VCSEL 89, 92 and

photodetector 62, 90 because the distance between VCSEL 89, 92 and photodetector

62, 90 are fairly precise based on the photo-optical alignment process used in

manufacturing the chip 130. Thus, a fairly accurate positioning of the chip 130 with

5     respect to the lead frame 128 during packaging will provide a reasonably accurate

passive alignment. Of course, fine alignment can be achieved using well-known active

alignment techniques. A further advantage of the coupling technique shown in Figure 7

is that no optics must be interposed between package 128 and ferrule 150 if the

coupling distance 152 is close enough. Of course, a flat transmissive surface 148 can

10    be easily achieved on package 128.

Fig. 8 illustrates a lead-frame package which can be used to interface with a

round multifiber ferrule such as the two fiber ferrule of Fig. 6 (a) Barrel 127 is designed

to precisely mate with the round ferrule of Fig. 6(b).
